

Do optical modules in switches consume a lot of power

Overview

These modules, such as SFP, SFP+, QSFP, and CFP, consume power continuously. While individual units typically consume between 0.5 to 4 watts, large-scale deployments with thousands of transceivers can lead to significant power bills and cooling overhead. A single data center can consume as much power as a city and it is estimated that data centers account for ~2% of the total US energy consumption. While the power usage efficiency has improved over time, especially in hyperscale data centers, the growth in FPP optics involve connecting switch Application-Specific Integrated Circuits (ASICs) to front-panel pluggable optical modules via electrical traces on the printed circuit board (PCB). As data rates increase, these longer electrical paths result in higher power consumption and signal integrity. Optical switches also offer substantial improvements in energy efficiency. Optical modules (SFP, SFP+, QSFP) are small, but when multiplied by thousands of ports they become a meaningful line item in both energy and heat budgets.
