

# What are the effects of scratches on the outer shell of a fiber optic cable connector

## Overview

Scratches are the most common type of end face defect, usually caused by improper cleaning or handling of optical connectors. Defects on a fiber end-face come in all types, shapes and sizes. They include scratches, cracks, and pits and contaminants like dirt, dust, oil and even salt. If you properly clean a fiber end-face with lint-free wipes and a specialized solvent designed specifically for fiber cleaning, it's. Dust particles, moisture, oils from fingerprints, and even microscopic scratches can disrupt the optical path, causing increased insertion loss (IL), degraded return loss (RL), and long-term reliability problems. A single-mode fiber core is just 9  $\mu\text{m}$  wide—smaller than a grain of dust—making even. Endface inspection is one of the most critical steps in fiber connector quality control. The primary inspection criterion for this zone is that it must be free from any scratches. even a small damage or imperfection on the connector end face can cause signal loss, increased reflectance, or high insertion loss. to prevent such issues, it's crucial to.
