

Why not use multimode fiber optic transmission

Overview

Multimode fiber has a larger core (typically 50 or 62.5 microns) and can carry multiple light signals, usually LEDs, at once. While that's great for short distances, those overlapping signals can bump into each other and cause distortion over longer distances. This keeps the signal tight and strong, making it ideal for long. In this exploration, we delve into the limitations of Multimode Fiber (MMF), where bandwidth is not just a number, but the lifeblood of communication speed and data throughput. Many engineers assume multimode fiber should have disappeared from modern data centers once high-speed single-mode optics became widely available. Multi Mode Fiber: Core-to-cladding diameter is. There are two main types of fiber optic cables: single mode and multimode. Because light doesn't bounce around inside the core, signal loss stays very low, allowing ultra-long-distance transmission.
